The information in this publication has been developed in consultation with experienced rangelands field staff providing services to the East Kimberley pastoral leases and with reference to Range Condition Guides for the West Kimberley Area, WA (Payne, Kubicki and Wilcox 1974) and Lands of the Ord–Victoria Area, WA and NT (Stewart et al. 1970).

The authors would like to thank all those who provided valuable feedback on the design and content of this guide, including Andrew Craig, David Hadden and Matthew Fletcher (DAFWA Kununurra), Simon Eyres (DAFWA Photographic Unit), Alan Payne (retired DAFWA rangelands advisor), and members of the Halls Creek—East Kimberley Land Conservation District.

This project was funded by Rangelands NRM WA using National Action Plan for Salinity and Water Quality funding. Rangelands NRM WA regards this project as a strategic investment which will contribute to an improved understanding and awareness of pasture condition in the Ord Catchment, leading to improved land management in that area. Rangelands NRM WA contracted the Department of Agriculture and Food WA to undertake the project.

Funding for the National Action Plan for Salinity and Water Quality was provided by the Australian and Western Australian Governments.

Introduction

This guide has been produced as a tool for assessing pasture condition over a range of pasture types in the Ord River catchment. A pasture type is a distinctive mix of plant species, soil type and landscape position. For example, the Mitchell Grass Alluvial Plain Pasture type is a mixture of Mitchell grasses and other species occurring on black soil alluvial plains.

Pasture condition is an important factor affecting the potential of the rangelands for animal production and is a useful indicator for the sustainability of production.

Why use this condition guide?
Rangelands are complex and diverse and condition assessment may seem complex and cumbersome, but with practical experience it is possible to evaluate the pasture condition consistently. This guide provides a method, supported with photographic examples, that allows users to readily see changes in pasture condition. It provides some early indications of when management changes are needed and helps users ‘tune’ their eyes to some of the key indicators of pasture condition.

Who is this guide for?
This guide is for pastoralists, resource managers, agency staff and others with an interest in the productivity and maintenance of rangeland plant communities. It can be used as a field reference for pasture condition assessments and as an aid to field training of agency or other staff.

What is pasture condition?
Pasture condition describes the current condition of the vegetation compared with the optimal condition that could be expected taking the potential of the site into account. The term ‘health’ is sometimes used, meaning that all parts that make up the whole are present and working well together. Pasture condition is rated as good, fair or poor in this guide, depending on how close the current condition is to the optimal condition.
Assessment of pasture condition rates vegetation based on the degree of departure from optimal condition through to total vegetation removal; condition classes are therefore relative. If a pasture site is described as being in good condition, the description is relative to the kind and amount of native vegetation that particular site is capable of producing.

**Pasture condition declines when:**
- desirable species are replaced by less desirable species;
- reduced plant cover increases the proportion of bare soil;
- erosion accelerates;
- production of palatable perennial species declines; or
- any combination of these effects occurs.

**States and transitions—are changes in pasture condition reversible?**
While a key assumption of pasture management is that all changes in condition are reversible given sufficient time, experience in the Kimberley and elsewhere shows that this may not always be the case. Changes in the composition of the rangeland as a consequence of various pressures (grazing, fire and drought) may not be directly reversible. Once the pressure eases, the perennial species that were lost when condition declined may be replaced by different perennial species (usually of a lower grazing value), and alternative stable situations (defined as ‘states’) may be established. Change from one state to another is referred to as a ‘transition’. These new states can be relatively resistant to change, creating essentially permanently altered pasture types that usually have a lower grazing value than the original pasture.

**When is the best time to assess pasture condition?**
Pasture condition can be assessed at any time of the year, since it depends on the species present and their density rather than on grass bulk (biomass). However, it is usually easier to identify particular species early in the season; later in the season, fire or heavy grazing can make identification difficult.
How often should pasture condition assessments be done?
The frequency of assessments depends on how quickly the pasture condition is changing. Yearly assessments allow early changes to be detected; on the other hand, since change is sometimes gradual, it may be easier to detect over intervals of several years.

Choosing sites for pasture condition assessment
When choosing sites to assess, consider your reasons for doing the assessment. Are you interested in a ‘hot’ spot where problems are evident and where you would like to judge change over time? If so, a single site monitored over a number of years would best serve your purpose. Alternatively, if you want to assess the ‘average’ condition of a paddock or management unit, you would be better to select a number of sites that are representative of the pasture types and conditions in that paddock.

Variability is normal in rangelands. No matter how hard you try to select a uniform site to assess, you will find variation in the species present compared to nearby areas, and variation in other aspects such as grazing pressure. Don’t worry about this. What is important is that your assessment sites are representative of the pasture type and condition of that area.

If there are two or more distinct pasture types in the area you are interested in, consider selecting a site to assess within each type. Avoid sampling across the boundary between different pasture types (e.g. where Ribbon Grass Pasture grades into Hard Spinifex Pasture).

Keeping track of changes
Recording the pasture condition at the same site over a number of years will show whether condition is improving, declining or staying the same. In conjunction with stock management and climate records, monitoring pasture condition enables the impact of management practices and seasonal conditions to be examined. One of the simplest ways to keep track of changes is to photograph the site each time you assess its condition and note down the date, the pasture type, condition and the reasons for your decision.
Pasture quality

Plant species occurring in a pasture type fall into three classes depending on their relative pastoral (forage) value—desirable, intermediate and undesirable. It is the proportions of these three classes in a pasture that largely determine its condition.

Desirable species are usually perennial grasses. These live for more than one season. They last through the dry season, providing feed and protection from erosion. Intermediate and undesirable species may be annual or perennial. Annual grasses generally live for one season only. They can provide short-term feed following a good wet season, but have little bulk. Annual grasses tend not to last beyond the dry season, so provide little protection from erosion.

General characteristics of desirable, intermediate and undesirable species

</tbody>
</table>
Good pasture condition— what to look for

- Desirable species (for the pasture type you’re in) are dominant, vigorous and evenly spaced.
- Some intermediate perennial and annual grasses may be present.
- Undesirables are rare.
- Desirables are reproducing; seedlings or young plants may be present.
- Ground cover is optimal for the site. Sites with good soils and higher rainfall can generally support a higher density of plants than sites with shallow stony soils or lower rainfall.
- Where plants have been grazed down or burnt, the butts of desirables are frequent and evenly spaced.
Fair pasture condition—what to look for

Intermediates make up about 30 to 50% of the stand. Desirables and undesirables take up roughly equal proportions of the remaining space. or Intermediates dominate, with only a few desirables and undesirables. or Only desirables are present, but the density of plants is low, with substantial (or increasing) bare areas in between.

- Desirables may show signs of reduced vigour, e.g. smaller bases or fewer stems.
- Seedlings or young plants of desirable species may be hard to find.
- Ground cover is less than optimal for the site. There may be patches of annual grasses early in the season that dry up or get trampled and blow away, leaving areas of bare ground later in the year.
Poor pasture condition—what to look for

Undesirable and intermediate species dominate. or Undesirables dominate, as dense stands or with variable amounts of bare ground. or Bare ground dominates, with occasional desirables or other perennial species spaced far apart.

- Desirable species are rare or absent.
- Any desirables remaining are usually stunted and unproductive.
- Intermediate species may be present but are less frequent compared to fair condition.
- Ground cover may be sparse or patchy.
- Large bare areas may be evident, particularly later in the season when the annual grasses have dried up or been trampled and blown away.
Why pasture type is important in assessing pasture condition

Different pasture types feature different species mixes; what you would expect to see at a site in good, fair or poor condition depends on what pasture type occurs there. This guide provides descriptions and photographic examples of good, fair and poor pasture condition for thirteen of the most common pasture types in the Ord River catchment. Correctly identifying the pasture type before you do the condition assessment ensures that you consult the descriptions and photos applicable to the site.

A short list of common species is provided for each pasture type, grouped into desirables, intermediates and undesirables. This list tells you how desirable a particular species is considered to be for a given pasture type. It is the relative proportions of desirables, intermediates and undesirables that largely determine pasture condition at a site.

Appendix A provides a list of all the species referred to in this guide, arranged by common name.

Using ‘identifier’ grasses to help determine pasture type

Certain grasses (called ‘identifier’ grasses) are typically associated with (although not limited to) certain pasture types. Identifier grasses are useful for determining pasture type because they tend to be present regardless of pasture condition. They will be easiest to find in good condition, and are usually still common in fair condition. As the pasture approaches poor condition, identifier grasses are sometimes present only as a few scattered plants or butts, and you may have to look hard to find them.

The key on the following pages uses soil type and position in the landscape, along with identifier grasses, to distinguish between the thirteen pasture types included in this guide. Keep in mind that a grass which is an identifier for one pasture type can also be present as a component of other pasture types. For this reason it is important that you follow the sequence of the key to determine soil group and landscape position before you look for the identifier grasses listed.
Key to determining pasture type

A pasture type is a distinctive mix of plant species, soil type and position in the landscape.
A pasture type is a distinctive mix of plant species, soil type and position in the landscape.

**soil type + position in landscape + identifier grass(es) → pasture type**

Working through a series of questions can help you determine the pasture type.

**Example 1: Hard Spinifex Hill Pasture**
- **Soil type**: shallow and rocky
- **Identifier grass**: Hard Spinifex
- **Position in landscape**: hills, ranges and footslopes

**Example 2: Hard Spinifex Plain Pasture**
- **Soil type**: Variable depth sands or loams, frequently rocky
- **Identifier grass**: Hard Spinifex
- **Position in landscape**: plains – level to undulating

The pasture type name is given according to the identifier grass or grasses and the position in the landscape.
Observe the features of the site

Go through steps one to four on this page, observing the features of the chosen site, then follow the key starting on the next page using your observations.

1. **Is the soil...**
   - black, grey or brown and heavy (high clay content)?
   - or
   - red, yellow or brown and sandy?
   - or
   - red, yellow or brown and loamy, gravelly or rocky?

2. **Is the position in the landscape more of...**
   - a hill?
   - or
   - an upland (or plateau)?
   - or
   - a plain?

3. **Are the perennial grasses spinifex?**
   - No (not spinifex) ---- These grasses can be found on most soils
   - Yes (spinifex) ---- Spinifex grasses are rarely seen on heavy soils

4. **What grasses can you see?**

   **Some commonly observed grasses:**

   *Note that these grasses are common examples, the list isn’t comprehensive of all grasses that occur in the region.*
Is the soil...

...black, grey or brown and heavy (high clay content)?

‘Black’ soil group

Curly Spinifex
Plain Pasture

If Soft Spinifex Pasture description and photos don’t seem right, check the description for Curly Spinifex Plain Pasture
Try to choose the most dominant grass. If it is too hard to choose, you may be looking at (1) pasture in fair to poor condition or (2) an uncommon pasture type.

- Use your general knowledge of desirable, intermediate and undesirable grasses to make an assessment of pasture condition. Check all pasture descriptions in the guide.
- Still not satisfied? Contact DAFWA for help with uncommon pasture types. Advice and assistance are available from Rangelands Development Officers at your local district office.

Note: check the Ribbon Grass Pastures description as well as the Arid Short Grass Pastures description because Arid Short Grass Pastures can be deceptively similar to Ribbon Grass Pastures in poor condition.

Mitchell Grass Upland Pasture
Mitchell Grass Alluvial Plain Pasture
Ribbon Grass Alluvial Plain Pasture
Mitchell Grass Upland Pastures

Occurrence
Mitchell Grass Upland Pastures are tussock grasslands with scattered small trees that occur on flat to undulating upland plains. The soils of the uplands are drier and stonier than those of black soil alluvial plains.

Pasture condition
**GOOD**—Desirable Mitchell grasses (Barley Mitchell and/or Hoop Mitchell) are usually dominant when this pasture type is in good condition. Mitchell Grass tussocks are healthy and evenly spaced. There may be small amounts of other desirable perennial grasses, such as Bundle-Bundle and Ribbon Grass. Isolated plants of Feathertop, an undesirable perennial grass, are usually present, even in good condition. Annual grasses and herbs will occupy the ground space between perennial tussocks in the late wet to early dry season. As grazing of palatable annual species (such as Flinders grasses) progresses into the dry season, small bare areas are created between the perennial tussocks.

**FAIR**—A reduction in density and vigour of Mitchell grasses and other desirable perennial grasses will occur as pasture condition declines from good to fair, and the tussocks will not provide an even cover. Less palatable perennial grasses such as Native Millet become more apparent, and the stand is likely to be dominated by this and other intermediates such as Bull Mitchell Grass or Silky Browntop. Annual Sorghum can occupy the increased space between the perennial tussocks. Unpalatable perennial grasses such as Feathertop increase in frequency, and may occupy up to an equal amount of ground space as the desirable species present.

**POOR**—Further deterioration to poor condition results in the almost complete loss of Mitchell grasses and other desirables, and a significant increase in bare ground. The pasture is dominated by Feathertop or annual grasses, though some intermediate perennial grasses can still be present. Non-grass plants (woody and/or weedy species) may increase.

Pastoral value
Pastoral value is high when in good condition, although the uplands are slightly less productive than the alluvial plains. As Mitchell Grass presence declines, pasture value also declines because the desirable grasses are replaced by less palatable perennial grasses or undesirables like Feathertop. Increased amounts of annual grasses can provide good feed for stock, particularly early in the year, but the bulk depends on the season. In below average rainfall years, the bulk and vigour of annual grasses will be much reduced.
Mitchell Grass
Upland Pasture—
good condition
(low utilisation)
September 2006

A There is a dense coverage of Mitchell Grass and other desirables.

B Red Flinders Grass (an intermediate) and other annual grasses are growing in between the perennial grass tussocks.

Tussock density is optimal for the site.
Mitchell Grass  
Upland Pasture—good condition  
(moderate utilisation)  
June 2003

A There is a dense coverage of desirable Mitchell Grass and Bundle-Bundle tussocks, grazed down to between 20 and 40% utilisation.

B Annual grasses are filling the spaces between the perennial grass tussocks.

Tussock density is optimal for the site.
Mitchell Grass Upland Pasture—fair condition
May 1998

A There is a reduced density of desirable Mitchell grasses.
B Native Millet, an intermediate, is more apparent.
C Woody plants, in this case Rubber Bush, are taking up some of the ground space.

The increased space between perennial grass tussocks is occupied by annual grasses.
Mitchell Grass Upland Pasture—poor condition
July 1996

A Undesirable Feathertop and annual species dominate.
B There are large areas lacking any perennial grass cover.
C Desirable species are not easy to find, and intermediate species such as Native Millet lack vigour.
D Prickle Bush, an indicator of heavily used black soils, is present.

Mitchell Grass Alluvial Plain Pastures

Occurrence
Mitchell Grass Alluvial Plain Pastures are tussock grasslands that occur on level plains with gilgai microrelief. Gilgai (crabhole country) has a markedly undulating surface caused by swelling and shrinking of the clay soil during alternating wet and dry seasons. There are sometimes scattered small trees (e.g. bauhinias) in these pastures.

Pasture condition
Good—Desirable Mitchell grasses (Barley and/or Hoop Mitchell) usually dominate in good condition, often with small amounts of other desirable perennial grasses such as Bundle-Bundle and Ribbon Grass. Mitchell Grass tussocks are healthy and evenly spaced. Annual grasses, such as Red Flinders Grass and Kimberley Couch, and herbs may occupy the spaces between perennial tussocks early in the year. As the dry season progresses, the groundcover between Mitchell Grass tussocks is reduced as annual grasses are grazed.

Fair—Density and vigour of desirable Mitchell grasses and other desirable perennial grasses fall as pasture condition declines from good to fair. Bull Mitchell Grass is considered an intermediate grass in this pasture type, and it or other intermediates such as Native Millet may become prominent. Feathertop, an undesirable perennial Threeawn, may increase. Red Flinders Grass or less desirable annual plants may occupy the increased space between perennial grass tussocks.

Poor—Further deterioration to poor condition results in almost complete loss of the Mitchell grasses and other desirables, and a significant increase in bare ground. Two things may happen: (a) the pasture may be dominated by non-grass plants (woody and/or weedy species); or (b) the pasture may be completely dominated by Feathertop. Both situations are equally unproductive.

Pastoral value
Productive and resilient under grazing, good condition pastures dominated by Mitchell Grass have high pastoral value. As Mitchell Grass density declines, pastoral value falls because less productive perennial grasses (those with reduced pasture bulk and resilience) or undesirables, like the unpalatable Feathertop, take over. Red Flinders Grass provides good feed for stock, particularly early in the year, but its bulk depends on the season. In below average rainfall years, little Red Flinders Grass may be produced.
Mitchell Grass
Alluvial Plain Pasture—
good condition
(low utilisation)
May 2008

A  There is a dense coverage of
Barley Mitchell Grass and other
desirables.

B  Red Flinders Grass, an
intermediate annual grass, is
growing vigorously in between
the perennial grass tussocks.

Ground cover is optimal for the site.
Mitchell Grass
Alluvial Plain Pasture—
good condition
(high utilisation)
May 2008

A There is a dense coverage of desirable Mitchell Grass tussocks, grazed down to about 60% utilisation.

B The annual grasses growing in between the perennial grass tussocks have been largely removed by grazing.

Tussock density is optimal for the site; however, year-in, year-out utilisation at this level would lead to an increase in bare ground and pasture condition decline.
Mitchell Grass
Alluvial Plain Pasture—fair condition
May 2008

A The density of desirable Mitchell grasses is reduced.
B Intermediate perennial grasses, such as this Silky Browntop, are becoming more prominent.
C There is an increased presence of Feathertop, an undesirable perennial grass, and non-grass plants.
Mitchell Grass
Alluvial Plain Pasture—poor condition
May 2008

A Desirable species such as this Mitchell Grass are not easy to find; they occur in small patches and lack vigour.

B Bare ground is frequent, with some large patches.

C The relative frequency of non-grass plants has increased.

D The remaining grasses are mostly annual species, such as Kimberley Couch; they are patchy and lack vigour.

Ribbon Grass Alluvial Plain Pastures

Occurrence
Ribbon Grass Alluvial Plain Pastures occur on level alluvial plains throughout the East Kimberley. They are found on deep grey or brown cracking clays and occur as tussock grasslands, sometimes with a variable cover of trees, for example eucalypts and baumhinas. These pastures occupy a similar niche to Mitchell Grass Alluvial Plain Pastures. The main difference is that here Mitchell grasses are totally absent; additionally, some tree cover is a little more likely and gilgai microrelief is not always evident.

Pasture condition

GOOD—When in good condition, these pastures are dominated by Ribbon Grass. Bundle-Bundle is also often present. Isolated plants of intermediate value species such as Native Millet (more common in higher rainfall areas), Silky Browntop or Annual Sorghum may be present. There is little bare ground visible unless the pasture is heavily grazed, and the plants appear vigorous.

FAIR—Prolonged heavy grazing on the preferred Ribbon Grass and Bundle-Bundle plants reduces their density and in fair condition the intermediate value species are more prominent. The lower density and smaller size of desirable plants allow an increase in undesirable plants such as Feathertop and Rubber Bush. Bare patches may become more obvious.

POOR—In poor condition, Ribbon Grass and Bundle-Bundle plants are infrequent, often stunted and lacking vigour. Sometimes undesirable perennial species such as Feathertop can dominate. Alternatively, there may be significant bare areas or large areas with annual grasses such as Kimberley Couch. Intermediate value species have declined or may have been grazed out and grazing may even be evident on Feathertop and Rubber Bush, species of low palatability.

Pastoral value
Ribbon Grass Alluvial Plain Pastures have a high pastoral value when in good condition. Ribbon Grass plants can be killed by repeated prolonged heavy grazing, especially during dry years.
Ribbon Grass
Alluvial Plain Pasture—good condition
May 2008

A  High density and even spacing of Ribbon Grass plants, which appear healthy.

B  Only a small amount of undesirable species such as Feathertop.

C  The Prickle Bush growing in the background is an indicator of the heavy soils on which this pasture type is found.

Mitchell grasses are not evident, confirming the pasture type determination.

This pasture is lightly grazed; however, the high density of desirables would still be obvious under a higher utilisation rate, so the condition would still be assessed as good.
Ribbon Grass
Alluvial Plain Pasture—fair condition
June 2008

A The density and vigour of desirable perennial grasses are reduced.
B There is an increased number of undesirable plants such as Feathertop.
C There are more patches with no perennial grass cover.

Mitchell Grass butts are not evident, confirming the pasture type determination.
Ribbon Grass
Alluvial Plain Pasture—
poor condition
May 2008

A  Ribbon Grass is sparse and stunted, showing evidence of heavy grazing.
B  The undesirable perennial, Feathertop, remains.
C  There are large areas of bare ground.

Mitchell Grass butts are not evident, confirming the pasture type determination.

‘Sandy’ soil group
Curly Spinifex Plain Pasture
Tippera Tall Grass Plain Pasture
Curly Spinifex Plain Pastures

Occurrence
Curly Spinifex Plain Pastures are widespread on level to undulating plains throughout the East Kimberley. They are found on a range of sandy or stony soils. In the north, they occur in eucalypt woodlands. In the drier southern areas they occur with scattered wattles and eucalypts, or as treeless hummock grasslands.

Pasture condition
GOOD—In good condition, Curly Spinifex dominates and is evenly distributed. Ribbon Grass may also be common; its presence is largely influenced by moisture availability and past stock grazing pressure. A range of other desirable and intermediate perennial species may be present, with palatable annual grasses often occurring in the spaces between the perennial grasses. Desirable species are vigorous and seedlings or young plants of Curly Spinifex and Ribbon Grass are often present, depending on the seasonal conditions and time of year.

FAIR—In fair condition, the Curly Spinifex stand is uneven, with larger bare areas developing between plants. Ribbon Grass may be well grazed and infrequent. Desirable perennial grasses show some loss of vigour and there is an increase in the presence of less palatable perennial species such as Wire Grass.

POOR—In poor condition, desirables (e.g. Curly Spinifex and Ribbon Grass) are rare. The pasture may still be quite dense but is dominated by undesirables and intermediate value annuals, such as Threeawn species, Annual Sorghum and Kimberley Couch. Some intermediate value perennial grasses (e.g. Wire Grass) may be present.

Pastoral value
Curly Spinifex Plain Pastures have a low pastoral value, although value is increased if there is a high density of Ribbon Grass in the stand. These pastures can also provide a valuable drought reserve. Too frequent burning, burning at the wrong time, or heavy grazing following fire causes desirables such as Curly Spinifex and Ribbon Grass to decrease or disappear.
Curly Spinifex
Plain Pasture—good condition
May 2008

A Curly Spinifex, a desirable in this pasture type, is dominant; individual adult plants are healthy and some younger plants can be seen.

B Only small, evenly spaced areas of bare ground are evident.
Curly Spinifex Plain
Pasture—fair condition
August 2008

A Curly Spinifex is present, but the density is reduced and coverage is patchy.

B Patches of bare ground are uneven and large.

C Some undesirable species are present, such as Threeawns.
Curly Spinifex Plain Pasture—poor condition
May 2008

A Curly Spinifex plants are infrequent.
B Undesirables, such as Threeawns, make up approximately half the stand.
C Patches of bare ground are larger.
D Rice Grass, a coloniser of bare areas, is present.

</table>
Occurrence
Tippera Tall Grass Plain Pastures occur on level to gently undulating plains in wetter areas of the East Kimberley. They occur as grasslands in eucalypt woodlands on red to yellow sandy and loamy soils. There may be patches of heavier soil within the typical sands and loams.

Pasture condition
**GOOD**—In good condition, dominant species can include Kangaroo Grass, Plume Sorghum, White Grass and Ribbon Grass. Other perennial grasses such as Black Speargrass and Bundle-Bundle may be present in small patches and can be scattered throughout the stand.

**FAIR**—As the palatable grasses are grazed out, intermediate species such as Wire Grass become more obvious and may dominate the stand in fair condition. Threeawns and Annual Sorghum (both considered undesirables in this pasture type) may begin to increase.

**POOR**—In poor condition, the space between perennial grass tussocks increases due to grazing and the stand is usually dominated by annual grasses, particularly Annual Sorghum. Annual Sorghum is only palatable when very young, and it has little bulk and very low nutritional value after it has hayed off. Other undesirables such as Threeawns are often present. There may be significant areas of bare ground.

Pastoral value
Tippera Tall Grass Plain Pastures are considered to have moderate pastoral value when in good condition. Kangaroo Grass has been reported to decline quickly under heavy grazing, however the pasture appears to be quite resilient under low stocking rates in the East Kimberley. Annual grasses are considered only marginally more productive than bare ground in this pasture type.
Tippera Tall Grass
Plain Pasture—good condition
June 2008

There is a dense coverage of Kangaroo Grass, a desirable perennial in this pasture type.
Tippera Tall Grass
Plain Pasture—
fair condition
June 2008

A Kangaroo Grass, a desirable, is still present, making up about a third of the stand.

B Annual Sorghum and Threeawns, both undesirables, are becoming prominent.

C Pan Wandarrie Grass, an intermediate, has increased.
Tippera Tall Grass
Plain Pasture—
poor condition
November 2008

A The desirable Kangaroo Grass is still present, but infrequent.

B The undesirable Annual Sorghum has increased and is now dominant.

‘Red’ soil group—Spinifex

Curly Spinifex/Annual Sorghum Hill Pasture
Hard Spinifex Hill Pasture
Hard Spinifex Plain Pasture
Soft Spinifex Pasture
Curly Spinifex/Annual Sorghum Hill Pastures

Occurrence
These pastures are a mixture of Curly Spinifex and Annual Sorghum, occurring with a tree layer of eucalypts and small terminalias. They are found in various locations north of Halls Creek, and are most common on stony hillslopes with shallow soils.

Pasture condition
**GOOD**—In good condition, these pastures are dominated by Curly Spinifex and Annual Sorghum. Curly Spinifex is quite obvious among the taller sorghum plants, and a small amount of other perennial grasses may be present.

**FAIR**—Condition decline in this pasture type is marked by a reduction in frequency of Curly Spinifex plants, with Annual Sorghum becoming far more obvious in fair condition as a result. Other perennial grasses such as White Grass and Black Speargrass may also become more apparent in fair condition.

**POOR**—In poor condition there are few Curly Spinifex plants left. Annual Sorghum, an intermediate, and undesirables such as Hard Spinifex or Threawns, make up the bulk of the stand.

Pastoral value
This pasture type is of low forage value and a decline in condition reduces the value even further. However, the relative inaccessibility of this pasture type means that it is unlikely to be heavily grazed under most circumstances. Excessive pressure on this pasture due to frequent fire or hot fire in conjunction with grazing reduces the frequency of Curly Spinifex plants. The amount of Annual Sorghum varies in response to rainfall and fire history, and its height varies in response to rainfall: it usually grows much taller in the higher rainfall areas in the north than it does further south.
Curly Spinifex/Annual Sorghum Hill Pasture—good condition
May 2008

A Curly Spinifex, a desirable, is dominant.

B Annual Sorghum, an intermediate, is growing among the Curly Spinifex.

C Only a few other perennial grasses are present, in this case, Black Speargrass.

Ground cover is optimal for the site, considering the poor soil and slope.
Curly Spinifex/Annual Sorghum Hill Pasture—fair condition
March 2009

A Annual Sorghum, an intermediate, dominates.

B The desirable Curly Spinifex remains scattered among the Annual Sorghum.
Curly Spinifex/Annual Sorghum Hill Pasture—poor condition
March 2009

Intermediate and undesirable grasses dominate at this site. The desirable Curly Spinifex is present only as isolated plants.

A Annual Sorghum, an intermediate, is prominent.

B Hard spinifex, an undesirable, makes up a high proportion of the stand.

</tbody>
</table>
Occurrence
Hard Spinifex Hill Pastures occur as hummock grasslands on hills and ranges in the East Kimberley. They are found on shallow, rocky soils. Scattered shrubs and trees (e.g. Snappy Gum) may be present.

Pasture condition
**GOOD**—In good condition, there is an even coverage of Hard Spinifex plants. A few palatable perennial grasses, annual grasses and herbs may be scattered among the spinifex clumps, but tend to be concentrated along the drainage lines.

**FAIR**—Hard Spinifex Hill Pastures are not commonly seen in fair condition away from the creeklines. Grazing pressure is concentrated along creeklines in this pasture type and therefore deterioration in pasture condition will be most noticeable there. The coverage of spinifex plants away from the creeklines may appear patchy. Palatable perennial species show reduced frequency and vigour, and undesirables make up an increased proportion of the non-spinifex species present.

**POOR**—Hard Spinifex Hill Pastures are rarely seen in poor condition away from the creeklines. Palatable perennial species are likely to be absent in poor condition. The risk of erosion in the creeklines is increased and only a few undesirable perennial and scattered annual grasses remain. There may be large bare areas between spinifex plants away from the creeklines.

Pastoral value
Pastoral value is very low. Hard Spinifex is unpalatable at most stages of growth, and palatable plants are too infrequent to support grazing for any length of time. The upper slopes of these pastures are largely inaccessible to stock. Condition decline due to grazing is most likely to be seen in the more accessible areas of the pasture, such as shallow drainage lines where the more palatable plants tend to occur.
A There is an even coverage of Hard Spinifex plants, taking into account how steep and stony the site is.

B Bare areas are small and evenly distributed between spinifex hummocks.

Hard Spinifex Hill Pasture—fair and poor condition

As Hard Spinifex Hill Pastures are usually only seen in good condition, no photos of fair or poor condition are included in this guide.

Hard Spinifex Plain Pastures

Occurrence
Hard Spinifex Plain Pastures occur on level to undulating plains in drier areas of the East Kimberley. They are found on loamy and sandy soils which are generally shallow or stony. They occur as hummock grasslands, with occasional trees or shrubs.

Pasture condition
GOOD—In good condition, there is an even coverage of Hard Spinifex plants. A few palatable perennial grasses, e.g. Silky Browntop, Ribbon Grass and Soft Spinifex, may occur in low numbers between spinifex hummocks but will tend to be concentrated along the drainage lines or under trees. A variable cover of palatable intermediate value annual grasses such as Limestone Grass may also be found for a short time following a good wet season.

FAIR—Hard Spinifex is generally ignored by stock, so it is mainly the in-between species that cattle will graze when on Hard Spinifex pastures. For this reason, a decline from good towards fair condition is usually accompanied by a reduction in frequency and vigour of the palatable species. The coverage of spinifex plants may appear patchy or uneven, with the areas in between supporting a sparse cover of annual and undesirable perennial grasses (e.g. Threawns). Poor post-fire grazing management can cause an uneven appearance in this pasture type.

POOR—In poor condition, larger bare patches occur among the spinifex. Palatable grasses lack vigour or are absent. Any non-spinifex species present tend to be undesirable perennial grasses, or annuals with low fodder value. The abundance of annual grasses is dependent on the season.

Pastoral value
Hard Spinifex Plain Pastures have a very low pastoral value. Hard Spinifex is unpalatable at most stages of growth, although cattle may sometimes graze spinifex plants regenerating after fire. Frequent burning of small areas off tracks can lead to a concentration of stock on the regenerating pasture and a decline in condition. Stocking rates also need to be managed to prevent the few palatable species present being grazed out. Despite its low palatability, Hard Spinifex is considered desirable in this pasture type because it helps control erosion.
Hard Spinifex
Plain Pasture—
good condition
May 2008

A  There is an even coverage of Hard Spinifex, a desirable, with only small spaces between hummocks.

B  The palatable perennial Silky Browntop is present and appears vigorous.
Hard Spinifex
Plain Pasture – fair condition
May 2008

A There is an uneven coverage of Hard Spinifex.

B There are increased spaces between spinifex plants with only annual species present, in this case an undesirable annual Threeawn.

There is a lack of palatable species growing between spinifex hummocks.
A There is a low coverage of Hard Spinifex.
B Other plants at the site are undesirables with low fodder value.
C There are large areas of bare ground.
D Some areas of the site are actively eroding.

</table>
Occurrence
Soft Spinifex Pastures are hummock grasslands with scattered trees and acacia shrubs. They occur on level to gently undulating plains and occasionally hills throughout the East Kimberley. Soils are usually well-drained sands and loams, and are sometimes rocky.

Pasture condition
GOOD—The dominant grass is Soft Spinifex when this pasture type is in good condition. Other perennial grasses including Ribbon Grass, Silky Browntop, Curly Spinifex and Woollybutt Grass may occur in low numbers among the spinifex. Annual grasses such as Limestone Grass may also be present. Plants are vigorous, productive and evenly spaced. The size and density of plants in the stand is dependent on the length of time since fire, seasonal conditions, grazing pressure and time of year.

FAIR—As pasture condition declines from good to fair, less desirable species such as Threeawns and Wire Grass become more prominent, though Soft Spinifex is still dominant. Soft Spinifex plants may be less vigorous and other desirable species are hard to find. Turpentine Bush and other acacias may increase, making it difficult for stock to access the grass.

POOR—Soft Spinifex Pasture that has declined to poor condition will most likely be dominated by undesirable Threeawns and Wire Grass (an intermediate). There may be thick Turpentine Bush, making it difficult for stock to access the grass, or bare areas may have increased. Soft Spinifex Pasture in poor condition that is adjacent to Hard Spinifex pasture may be colonised by Hard Spinifex in the bare areas.

Pastoral value
Soft Spinifex Pastures are of moderate grazing value under low stocking rates when in good condition. Soft Spinifex Pastures are the most useful of the spinifex pastures, and are also regarded as a useful drought reserve. Heavy grazing, or grazing too soon after fire, can remove the Soft Spinifex plants and cause condition decline. Turpentine Bush and other acacias may increase after fire, making it difficult for stock to access the grass. Late season burning on a four – to six-yearly rotation is considered to be good practice, as it allows new seedlings to establish. The country should be spelled after burning until the grass seed has dropped.
Soft Spinifex Pasture—good condition
May 2008

A  There is a high density of the desirable Soft Spinifex, and the plants appear healthy.

B  Young Soft Spinifex plants are present.

There is a good coverage of Soft Spinifex, given that this photo was taken about two years after the site was burnt.
Soft Spinifex Pasture—fair condition
May 2008

A. The density of the desirable Soft Spinifex is reduced, though it is still the dominant grass.

B. Other desirable grasses, such as this Silky Browntop, are infrequent.

C. Undesirable Threeawn grasses can be seen in the stand.

D. Turpentine Bush has increased, reducing accessibility. The site still has good groundcover.
A The desirable Soft Spinifex plants are sparse and lack vigour.

B Hard Spinifex, an undesirable, has invaded the site; the undesirable annual Threeawn is also present.

C Large bare areas can be seen.

D There is a very thick stand of Halls Creek Wattle and Turpentine Bush, reducing accessibility and suppressing grass growth.

‘Red’ soil group—not spinifex

Ribbon Grass Pasture
Arid Short Grass Pasture
Black Speargrass Pasture
White Grass/Bundle-Bundle Pasture
Ribbon Grass Pastures

Occurrence
Ribbon Grass Pastures occur on level to gently sloping plains throughout the East Kimberley. They are found on sands, loams and occasionally clays. They grow as open grasslands, or as grassy woodlands with bauhinias, eucalypts, beefwood and other tree species.

Pasture condition
**GOOD**—In good condition, Ribbon Grass is dominant or co-dominant. Other co-dominants can be White Grass and Plume Sorghum in the higher rainfall areas, or Soft Spinifex and Curly Spinifex in the lower rainfall areas. Isolated intermediates such as Black Speargrass may also be seen. There is uniform tussock spacing and all plants are vigorous.

**FAIR**—Cattle preferentially graze Ribbon Grass and other palatable perennial species, so heavy continuous grazing will lead to a gradual decline in the size and vigour of desirables. Species in the pasture that are less preferred by cattle (e.g. Black Speargrass) increasingly dominate in fair condition. Small patches of bare ground may be present and the proportion of undesirables (e.g. Threeawns) in the pasture increases.

**POOR**—As the pasture condition declines further towards poor condition, desirable perennial grasses become small, stunted and sparse, or may even disappear completely with only dead butts remaining. Few if any seedlings or young plants of desirables are seen. Intermediates are scattered, having been exposed to higher grazing pressure in the absence of more palatable species. Undesirables, such as Threeawns, and annual grasses become more frequent. There may be large patches with little or no perennial grass cover, and the risk of erosion is increased, particularly if the annual grasses dry out and blow away.

Pastoral value
Ribbon Grass Pastures can include a wide variety of species, so the pastoral value can vary depending on which species are dominant. Ribbon Grass is a resilient and productive plant, with very high palatability early in the season: it is also sometimes eaten late in the season. Where it dominates, the pastoral value of good condition Ribbon Grass Pastures is high. As the condition declines, carrying capacity declines along with it because of the increased proportion of annual and undesirable species in the pasture.
Ribbon Grass Pasture—
good condition
June 2008

A  Dense, vigorous Ribbon Grass tussocks dominate the stand.

B  Only a few patches of Black Speargrass, an intermediate, can be seen.

No undesirables are obvious in the pasture.

This pasture is lightly grazed; however, the high density of desirables would still be obvious under a higher utilisation rate, so the condition would still be assessed as good.
Ribbon Grass Pasture—fair condition
May 2008

A Desirable perennial grasses (Ribbon Grass in this photo) are still present but are not dominant.

B Intermediates (such as these Black Speargrass plants) make up 30 to 50% of the stand.

C Some larger areas have annual grass cover only.
Ribbon Grass Pasture—poor condition
May 2008

A  There is a big patch of undesirable perennial grasses (Threeawns).

B  Large areas have patchy annual grass cover only, with bare spots developing.

C  Intermediate species, such as this Black Speargrass plant, are sparse.

Arid Short Grass Pastures

Occurrence
Arid Short Grass Pastures are grasslands dominated by short-lived perennial or annual grasses with scattered eucalypt trees. They occur on level to undulating plains. Soils are variable depth loams (sometimes calcareous) and the surface may be stony.

Pasture condition
GOOD—Limestone Grass is usually dominant when this pasture type is in good condition. Purple Nineawn, an intermediate annual grass, may also be common. Plants are robust and vigorous, and little bare ground can be seen unless the pasture is grazed down. Some perennial grasses, such as Ribbon Grass, Wire Grass, White Grass and Black Speargrass, may be present as sparse, isolated plants or scattered small patches.

FAIR—As pasture condition declines from good to fair, intermediate annual grasses such as Bunched Kerosene Grass become more common. Limestone Grass is still prominent, although the plants are likely to be less vigorous and bare areas may be visible. Less palatable perennial species such as Wire Grass, White Grass and Black Speargrass may still persist.

POOR—Further decline towards poor condition is signalled by large areas of bare ground and increased presence of unpalatable annual grasses such as Threeawns. Remaining perennial grasses are much reduced in vigour. In areas adjacent to Hard Spinifex pastures, Hard Spinifex may colonise the bare areas.

Pastoral value
The true extent of Arid Short Grass Pasture is the subject of current debate. Evidence suggests that many areas once considered to be Arid Short Grass Pasture are capable of supporting healthy stands of perennial grasses more characteristic of Ribbon Grass Pasture, if spelled to allow recovery. Ribbon Grass Pasture is a more resilient and a slightly more productive pasture type than Arid Short Grass Pasture.

Pastoral value for Arid Short Grass Pasture is moderate, however resilience is low. Though annual grasses such as Limestone Grass and Kimberley Couch can provide good feed for stock early in the year while still green, their bulk is variable. In below average rainfall years, very little annual grass may be produced. The small patches of the long-lived perennial grasses supply the bulk of the feed for the rest of the year. Limestone Grass and some other robust annual grasses can act as short-lived perennials under optimal conditions (i.e. in a run of good seasons).
Arid Short Grass Pasture—good condition
May 2008

A There is a dense coverage of Limestone Grass (a desirable) and other annual grasses.

B Undesirable species, such as this Threeawn, are sparse.

C Desirable perennial grasses (e.g. Ribbon Grass) can occasionally be found.

Ground cover is optimal for the site.
A The desirable Limestone Grass is still common, though its vigour and density are reduced; here it makes up approximately 30% of the stand.

B Intermediate annual grasses, such as Kimberley Couch, make up at least 30% of the stand.

C Undesirables, such as these Threeawns, are increasing.

D Black Speargrass, a less palatable perennial grass, persists.
Arid Short Grass
Pasture—poor condition
May 2008

A There are large areas of bare ground developing. Desirable annual grasses cannot be seen.

B The remaining perennial grasses are isolated and show poor vigour.

C There is an increased presence of Rice Grass, a coloniser of degraded areas.

Black Speargrass Pastures

Occurrence
Black Speargrass Pastures occur on plains and lower hillslopes throughout the East Kimberley. They are found on a variety of sandy to loamy soils and usually occur as grassy open eucalypt woodlands.

Pasture condition
GOOD—In good condition, these pastures are almost completely dominated by Black Speargrass. The plants are robust and, unless the pasture is regrowing after a fire, there is virtually no bare ground. Small amounts of other desirable perennial grasses such as White Grass and Ribbon Grass may be present, but generally do not comprise more than 20% of the stand.

FAIR—As pasture condition declines from good to fair, Black Speargrass remains dominant but its density is reduced, with gaps visible in the stand. Intermediate species such as Wire Grass, and undesirables such as Threeawns, become more prominent. Palatable perennial grasses, for example Ribbon Grass, are all but absent.

POOR—Poor condition is characterised by increasingly large areas with little or no perennial grass cover in between the Black Speargrass plants. These areas may support annual grasses early in the season, but often become bare later in the year as the annual grasses are grazed, trampled or dry up and blow away. While undesirable perennial grasses and a few scattered intermediates may be present, Black Speargrass remains the dominant perennial grass.

Pastoral value
Black Speargrass can be heavily grazed when young, especially when regenerating after fire. However, mature Black Speargrass is not preferred by cattle and so the value of the pasture largely depends on the other species found growing with it. When condition declines and undesirable or unpalatable species become more obvious, the carrying capacity of Black Speargrass Pastures is quite low.

It is possible that some Black Speargrass Pastures have become established on previously degraded red-soil areas that used to carry more productive pasture types.
Black Speargrass Pasture—good condition
May 2008

A  Black Speargrass, considered a desirable species in this pasture type, is the dominant species and forms a dense stand.

B  Only a few undesirable species, such as this perennial Threeawn, can be seen. Ground cover is very high.
Black Speargrass Pasture—fair condition
June 2008

A The desirable Black Speargrass is still the dominant perennial grass, but the stand is less dense.

B Small areas with no perennial grass cover are visible.

C There is an increased amount of the undesirable perennial Threeawn.
Black Speargrass 
Pasture—poor condition
July 2008

A Black Speargrass is still the dominant perennial grass, but the stand is broken up into smaller clumps.

B Large areas with no perennial grass cover are visible.

C Undesirables, such as this perennial Threeawn, are scattered throughout the Black Speargrass.

White Grass/Bundle-Bundle Pastures

Occurrence
White Grass/Bundle-Bundle Pastures occur on gently sloping plains and lower hillslopes throughout the East Kimberley. They are found on shallow to deep red loamy earths, often with stony surfaces. They occur as grasslands, or grassy woodlands with eucalypts, bauhinias and other tree species.

Pasture condition

**GOOD**—In good condition, White Grass is dominant. Bundle-Bundle, Ribbon Grass and the intermediate value Black Speargrass may occur on pockets of heavier soil. The desirable perennial grasses are robust and vigorous, forming a dense groundcover where grazing is light. There may be a few intermediate annual grasses present, such as Annual Sorghum, and a small number of undesirables such as perennial Threeawns.

**FAIR**—Under continued heavy grazing, the more palatable desirables such as Bundle-Bundle, Ribbon Grass and Plume Sorghum decline in frequency as condition approaches fair. The less palatable White Grass remains dominant but may appear patchy. Some intermediate value annual grasses may be present, but are often grazed out by the end of the growing season, leaving patches of bare ground. Annual Sorghum may increase, particularly after a run of good wet seasons. Undesirables, such as the unpalatable annual and perennial Threeawns, appear vigorous and make up an increased proportion of the stand.

**POOR**—In poor condition, larger patches of bare ground are visible. White Grass is still one of the most common species, though its density is reduced. Other desirables, such as Ribbon Grass or Bundle-Bundle, are absent or occur only as isolated butts. There is a high proportion of undesirables (e.g. Threeawns), though they do not form dense stands but rather stand out due to the lack of other species. A few scattered annual grasses may remain.

Pastoral value
White Grass/Bundle-Bundle Pastures have a moderate pastoral value. They are often surrounded by inaccessible country which may result in them carrying high concentrations of stock. In the East Kimberley, Bundle-Bundle can be hard to find, even when the pasture is in good condition.
A White Grass, a desirable in this pasture type, is the dominant species.

B Bare patches are small and infrequent.

C Only a few intermediate plants are present, in this case Black Speargrass.
White Grass/Bundle-Bundle Pasture—fair condition
June 2008

A The desirable White Grass is still dominant, but appears patchy.

B Larger areas with no perennial grass cover can be seen.

C The proportion of intermediates in the stand, in this case Black Speargrass, has increased.
White Grass/Bundle-Bundle Pasture—poor condition
June 2008

A The desirable White Grass is still common, but its density is reduced.

The site is dominated by:
B Large areas of bare ground;
C Undesirables, such as Threeawns; and
D Intermediates, such as this Black Speargrass.

Photographs of common species
Annual Sorghum (*Sorghum stipoideum*)

Annual Sorghum is palatable when young and green, and can be highly productive, however it hays off very quickly.

Seedheads: early stage (top), later stage (bottom)

Annual Sorghum (hayed off)

Base with stilt roots
Black Speargrass (*Heteropogon contortus*)

Black Speargrass has corkscrew-like seeds that form distinctive tangles (pictured on right) as the plant matures. The inset photograph shows the seedhead at an early stage of growth. Black Speargrass is nutritious when young or regenerating after fire, but becomes unpalatable as it matures.
Bull Mitchell Grass (Astrebla squarrosoa)

Bull Mitchell Grass is the least palatable of the Mitchell grasses and has coarser leaves than those of Barley Mitchell Grass.
Bunched Kerosene Grass (*Aristida contorta*)

Bunched Kerosene Grass is an unpalatable annual threeawn.
Bundle-Bundle (*Dichanthium fecundum*)

Bundle-Bundle is also known as Curly Bluegrass. The inset shows the distinctive ‘rabbit ears’ that are left behind after the seed has dropped.
Curly Spinifex (\textit{Triodia bitextura})

Curly Spinifex is grazed in association with more desirable grasses, despite its low palatability.
Feathertop (*Aristida latifolia*)

Feathertop is an unpalatable, perennial threeawn that occurs mainly on heavier soils. If you look at an individual seed, you will see that the column that joins the three awns to the pointed seed is twisted. The twisted column helps distinguish Feathertop from Unequal Threeawn (*Aristida inaequiglumis*), which does not have a twisted column.
Hard Spinifexes (*Triodia intermedia* and *Triodia wiseana*)

Winged or Lobed Spinifex (*Triodia intermedia*) is often found with a sparse low tree cover, including Snappy Gum (*Eucalyptus brevifolia*).

Limestone Spinifex (*Triodia wiseana*) is often associated with limestone and is widespread on rocky ridges and gravelly slopes.
Kangaroo Grass (*Themeda triandra*)

Kangaroo Grass is palatable and nutritious when young and green, becoming fairly coarse at maturity.
Kimberley Couch (*Brachyachne convergens*)

Kimberley Couch has distinctive upright seedheads (above) with three to five thin branches. It is palatable early in the season, but shatters and blows away as the season progresses.
Limestone Grass (*Enneapogon polyphyllus*)

Limestone Grass responds quickly to rain, and is nutritious fodder prior to flowering. It is usually an annual plant, but some individuals may survive for more than one season under optimal conditions. It may be dwarfed in poor soils or in below average rainfall years.
Ribbon Grass (*Chrysopogon fallax*)

Ribbon Grass is also sometimes called Golden Beard Grass. This example has only been lightly grazed.

A smaller, heavily grazed Ribbon Grass plant.
Soft Spinifex (Triodia pungens)

Soft Spinifex is regarded as the most useful of the spinifexes. It is drought resistant due to its deep root system.
Turpentine Bush (*Acacia lysiphloia*)

Turpentine Bush is often found in association with Soft Spinifex Pastures and may increase following fire. Its pods are very sticky when green.
Unequal Threeawn (*Aristida inaequiglumis*)

An unpalatable, perennial threeawn, with a close-up of the characteristic three-awned seedhead on the right. If you look at an individual seed, you will see that the column that joins the three awns to the pointed seed is not twisted. This feature helps distinguish Unequal Threeawn from Feathertop (*Aristida latifolia*), which has a twisted column.
White Grass (*Sehima nervosum*)

White Grass is fairly coarse with low palatability, but may be grazed at all stages in some pasture types as stocking pressure increases.
Wire Grass (*Eriachne obtusa*)

Wire Grass, also known as Northern Wandarrie Grass, has limited palatability in most situations and is considered a species of intermediate value.

¹ Common names are from Florabase (Western Australian Herbarium, 1998—), except where local usage differs (e.g. Bundle-Bundle).
² Alternative common names are from Florabase (Western Australian Herbarium, 1998—), Flora of Australia (2005) and Petheram and Kok (2003).
Appendix B: Further information and resources

Department of Agriculture and Food, WA
Advice and assistance on grazing land management is available from Rangelands Development Officers at your local district office. Kununurra District Office can be contacted on (08) 9166 4000. http://www.agric.wa.gov.au

Advice and assistance on plant identification is available from DAFWA at your local district office, or when Rangelands staff are visiting your lease.
• Take a photo if you have a camera handy.
• If you collect specimens and bring or send them in to us:
  – try to include culms (stems), leaves, seedheads and seeds (seeds are not always essential) for each grass specimen you collect;
  – dry and press specimens between sheets of newspaper prior to sending (preferred method), or, if bringing specimens in straight after collecting, keep them fresh in a sealed plastic bag in a cold esky or fridge.

Department for Planning and Infrastructure, WA
Guidelines and policies are available on a range of subjects from http://www.dpi.wa.gov.au, including best management practice guidelines for grazing cattle in the northern pastoral areas of WA and fire management for Kimberley pastoral rangelands.

Pastoral Lands Board
Pastoral lease reports for each lease are available to the lessee from the Pastoral Lands Board.

Appendix C: Glossary

**Alluvial plain:** a plain formed by the repeated deposition of sediment from a river when it floods.

**Annual:** a plant which grows from seed and completes its life cycle, including flowering and seeding, within one growing season. Some annuals can live longer than one year if growth conditions are favourable (see short-lived perennial).

**Awn:** a fine, hair-like structure that is attached to the flowering parts of many grasses. Threeawns are so named because of the three awns that are attached to the seed.

**Calcereous:** containing lime or limestone.

**Carrying capacity:** the number of stock units a paddock or management area can carry over the long term while maintaining or improving land condition.

**Co-dominant:** a species equally dominant with one or more other species in a pasture.

**Density:** the number of individuals of a certain species per unit area.

**Desirables:** those species in a given pasture type that are usually productive, highly palatable and perennial. Desirables generally decrease in frequency as grazing pressure increases because they are preferentially grazed by cattle.

**Grazing pressure:** the number of stock units grazing in relation to the amount of feed available.

**Herb:** a plant which does not produce a woody stem.

**Hummock grass:** spinifexes that grow together as large rounded mounds or ‘hummocks’ that can be up to several metres across, often forming rings around a central dead or decaying patch.

**Intermediates:** those species in a given pasture type that include moderately or slightly palatable perennial grasses and palatable annuals. These species may increase under heavy grazing at first, as stock concentrate on the more palatable desirable species. However, if grazing pressure continues and the desirable species are grazed out, intermediate value species will also start to decline.
**Palatability:** the degree to which a grazing animal finds a plant attractive to eat. This can vary with the age of the plant.

**Pastoral value:** the value of a pasture or an individual species for pastoralism, based on the quality and quantity of stock feed it provides.

**Pasture condition:** describes the current condition of the vegetation compared with the optimal condition which could be expected taking into account the potential of the site. Pasture condition is rated as ‘good’, ‘fair’ or ‘poor’ depending on how close the current condition is to the optimal condition.

**Pasture type:** a distinctive mix of plant species, soil type and landscape position.

**Perennial:** a plant which lives for three or more years. Plants that complete their life cycle over two years are biennial.

**Preferential grazing:** where stock selectively graze more palatable species before less palatable species. This can lead to the more palatable species being grazed out of a pasture.

**Resilience:** the ability of a plant, pasture or ecosystem to withstand disturbance.

**Short-lived perennial:** annual species that are able to live for more than one year if growth conditions are favourable. Also called a biennial.

**spp.:** abbreviation of species (plural), referring to more than one different species of the same genus; for example, *Triodia* spp. includes all kinds of spinifex grass.

**Tussock grass:** bunch grass, where the stems of the grass are bunched together forming a grass clump or ‘tussock’.

**Undesirables:** those species in a pasture type that are generally unpalatable. Undesirables include woody weeds and other weedy, prickly or toxic species which invade overgrazed pasture. Largely ignored by stock, undesirables tend to increase under prolonged heavy grazing, and in large numbers are an indication of poor pasture condition.

**Upland:** an area of land elevated above the plain.

**Utilisation:** the percentage of pasture grown in a year that is eaten by grazing stock.
Appendix D: References used in compiling this guide

Quick start guide

Step 1: Choose site(s) for assessment—see page 3.

Step 2: Determine the pasture type at the site—see pages 9-16.

Step 3: Look up the pasture condition description and photos for the relevant pasture type—see pages 17–87.

Step 4: Ask yourself the following questions:

• Q1. What is the site’s potential to store rainfall and grow grass (consider slope, aspect, soil type, rainfall zone)? This determines what the optimal pasture condition at the site could be. Pasture condition is rated as good, fair or poor depending on how close it is to optimal condition.

• Q2. What species are present? See photos of common species, starting from page 89, or use a field guide that includes pasture plants (see Appendix B).

• Q3. What proportion of the species that you can see are desirable, intermediate and undesirable for that pasture type? Refer to the species list for the relevant pasture type.

• Q4. How healthy do the desirable species look? Consider plant size and growth, leaf size and colour, number and size of seed heads and presence of young plants or seedlings.

• Q5. How much bare ground, or ground with no perennial cover, is there?

Step 5: Rate the pasture condition of the site as good, fair or poor—refer to the relevant pasture condition description and photos (pages 17–87). Which pasture condition statement (good, fair or poor) best describes your site?

Step 6: Record the pasture condition so you can monitor change over time—see page 3.
